Sustainability Report
Executive Summary

Background

In the spring of 2021, 6Connex, a Virtual Event Platform, contracted WSP, a world leading engineering and professional services consulting firm, to assess the greenhouse gas (GHG) impact of hosting virtual events on the 6Connex platform, in lieu of hosting on-site events. This engagement is a part of 6Connex’ corporate goal to communicate the sustainability benefits of its platform and virtual events.

For this study, WSP analyzed 7 unique events that were hosted on the 6Connex platform in 2020. WSP and 6Connex defined the boundaries of typical activities that occur during both on-site and virtual events. On-site event boundaries consider the emission impacts from travel, hotel, meals, waste, event space, and marketing materials. Virtual event boundaries consider the emission impacts from food, waste, marketing materials, virtual workstations, and the 6Connex servers. Primary data was compiled for this assessment. WSP conducted estimations which were validated by 6Connex to conduct this study when primary data was not available.

Results

- The results of this assessment show that for each study, conducting an event using the 6Connex Virtual Event Platform is significantly less carbon intensive than conducting one in person.
  - Travel to and from events was found to be the primary driver of carbon emission impact for most events. This impact increased when more attendees flew to an event.
  - Events which had a higher amount of local attendees resulted in lower emissions from travel.
  - The duration of the event had an overall impact on the emissions.
- The carbon impacts of these events should be viewed as emissions avoided rather than saved given virtual events do not reduce emissions.
- The following documents outlines the results of each analyzed event. Analysis compares the carbon emissions of on-site events versus events virtually hosted on the 6Connex platform. Equivalent carbon emissions avoided are also estimated for each analyzed event.
- The methodology and assumptions that were used to conduct this study are included below.
Insurance Organization

The world’s largest publicly traded P&C insurance company, headquartered in Warren, NJ, USA hosted their virtual event with 6Connex, attracting 3,001 attendees across four days. Due to converting their four-day event from in-person to virtual, they saved tremendously on lodging, travel, event space, and meals, all of which contribute to a large amount of total emissions.

Key Takeaways:

This virtual event emits ~9.5X less emissions than an in-person event

- Meals are the largest impact for virtual events ~80% and the largest to in-person events ~36%
- ~90% of attendees were local which minimized the carbon impacts from transportation

Transforming this event from in-person to virtual is equivalent to 987 acres of U.S. Forests
Event Details

Methodology

The following details the methodology used to calculate the emissions associated with an in-person and virtual event using the 6Connex web-based platform. The in-person events represents the likely event that would have been held in-person if not for 6Connex. Seven completed events were selected for analysis.

- Event Boundaries were determined at the beginning of this assessment to ensure a consistent and methodological approach in calculating both in-person and virtual events. An on-site event considered the emission impacts from travel, hotel, meals, waste, event space, and marketing materials. A virtual event considered the emission impacts from food, waste, marketing materials, virtual workstations, and the 6Connex servers.

- WSP requested event data from 6Connex for each selected virtual event. A data request was sent to 6Connex to provide details about each event. 6Connex provided all data for each event including, the IP addresses of each attendee, the physical location, number of attendees, days, marketing material, waste, food, and the server type used by 6Connex.

- Information was compiled and reviewed by WSP to ensure data completeness. Where data was not available, WSP made assumptions and estimations that were validated by 6Connex. A list of assumptions can be found in the Assumptions section of this document.

- A data calculation workbook was created to generate the carbon impacts for both in-person and virtual for each of the 7 events. This workbook calculated the results by multiplying the activity data by the corresponding emission factor. While there is not a specific method for calculating an event, this study follows leading GHG practices to calculate the GHG emissions associated with these events. A list of sources can be found within the Sources section of this document.

Assumptions

- Events Attendees: All 6Connex virtual events were assumed to have the same amount of attendees as in-person events.

- Attendee Location: IP addresses were provided by 6Connex for each event. IP addresses were used to identify the country of origin of each attendee.

- Event Location: Location of each physical event was provided by 6Connex.

- Transportation: Air travel to and from event was calculated by assuming major airport at country based on attendee IP addresses as well as the closest major airport to the event. An online calculator was used to determine the distance between airports. For local travel an estimation of travel type (Road, Rail, and Bus) and distance traveled was used to calculate the carbon emissions.

- Hotel and Meeting Space: Per 6Connex, 100% of hotel stays was classified as upscale. Meeting space assumed 50 sq. ft per attendee. All attendees assumed to have stayed at the hotel.

- Marketing Materials/Handouts: Assumes $30 per in-person attendee. $10 per virtual attended which includes shipping.

- Food: In-person attendees assumed $100 spend on meals per day. Virtual attendees assumed $10 spend per day.

- Waste: In-person attendees assumed 4.2 lbs. of waste per day. Virtual attendees assumed 1.63 lbs. per day. Assumptions were made for end of life scenarios, i.e. recycled vs. sent to landfill (US EPA)

- 6Connex Servers: Server types were provided by 6Connex. All 6Connex servers leverage Amazon Web Services (AWS). Servers were estimated to use 1.7 MWH/year. Emissions were calculated using location of server and energy usage. (US EPA eGrid)

- Virtual Event Space: The emissions from home energy consumption per user assumed 0.54 kg of CO2e per user per day.
## Sources per Impact Area

### Travel (United States): Flight, Car, Rail, Bus
